

# ADS824

## *SpeedPLUS*™ 10-Bit, 70MHz Sampling ANALOG-TO-DIGITAL CONVERTER

### FEATURES

- HIGH SNR: 59dB
- HIGH SFDR: 70dB
- LOW POWER: 315mW
- INTERNAL/EXTERNAL REFERENCE OPTION
- SINGLE-ENDED OR DIFFERENTIAL ANALOG INPUT
- PROGRAMMABLE INPUT RANGE: 1Vp-p or 2Vp-p
- LOW DNL: 0.3LSB
- SINGLE +5V SUPPLY OPERATION
- +3V DIGITAL OUTPUT CAPABILITY
- POWER DOWN: 20mW
- 28-LEAD SSOP PACKAGE

### APPLICATIONS

- MEDICAL IMAGING
- HDTV VIDEO DIGITIZING
- COMMUNICATIONS
- TEST EQUIPMENT

### DESCRIPTION

The ADS824 is a pipeline, CMOS analog-to-digital converter that operates from a single +5V power supply. This converter provides excellent performance with a single-ended input and can be operated with a differential input for added spurious performance. This high performance converter includes a 10-bit quantizer, high bandwidth track/hold, and a high accuracy internal reference. It also allows for the user to disable the internal reference and utilize external references. This external reference option provides excellent gain and offset matching when used in multi-channel applications or in applications where full scale range adjustment is required.

The ADS824 employs digital error correction techniques to provide excellent differential linearity for demanding imaging applications. Its low distortion and high SNR give the extra margin needed for medical imaging, communications, video, and test instrumentation. The ADS824 offers power dissipation of 315mW and also provides a power-down mode, thus reducing power dissipation to only 20mW.

The ADS824 is specified at a maximum sampling frequency of 70MHz and a single-ended input range of 1.5V to 3.5V. The ADS824 is available in a 28-lead SSOP package and is pin compatible with the 10-bit, 40MHz ADS822 and the 10-bit, 60MHz ADS823.

## ELECTROSTATIC DISCHARGE SENSITIVITY

This integrated circuit can be damaged by ESD. Burr-Brown recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

The information provided herein is believed to be reliable; however, BURR-BROWN assumes no responsibility for inaccuracies or omissions. BURR-BROWN assumes no responsibility for the use of this information, and all use of such information shall be entirely at the user's own risk. Prices and specifications are subject to change without notice. No patent rights or licenses to any of the circuits described herein are implied or granted to any third party. BURR-BROWN does not authorize or warrant any BURR-BROWN product for use in life support devices and/or systems.

# APPLICATION INFORMATION

## THEORY OF OPERATION

The ADS824 is a high-speed, CMOS analog-to-digital converter which employs a pipelined converter architecture consisting of 9 internal stages. Each stage feeds its data into the digital error correction logic ensuring excellent differential linearity and no missing codes at the 10-bit level. The output data becomes valid on the rising clock edge (see Timing Diagram). The pipeline architecture results in a data latency of 5 clock cycles.

The analog input of the ADS824 is a differential track and hold (see Figure 1). The differential topology along with tightly matched capacitors produce a high level of ac-performance while sampling at very high rates.

The ADS824 allows its analog inputs to be driven either single-ended or differentially. The typical configuration for the ADS824 is for the single-ended mode in which the input track-and-hold performs a single-ended-to-differential conversion of the analog input signal.

Both inputs (IN,  $\overline{\text{IN}}$ ) require external biasing using a common-mode voltage that is typically at the mid-supply level ( $+V_S/2$ ).

The following application discussion focuses on the single-ended configuration. Typically, its implementation is easier to achieve and the rated specifications for the ADS824 are characterized using the single-ended mode of operation.

## DRIVING THE ANALOG INPUT

The ADS824 achieves excellent ac performance either in the single-ended or differential mode of operation. The selection for the optimum interface configuration will

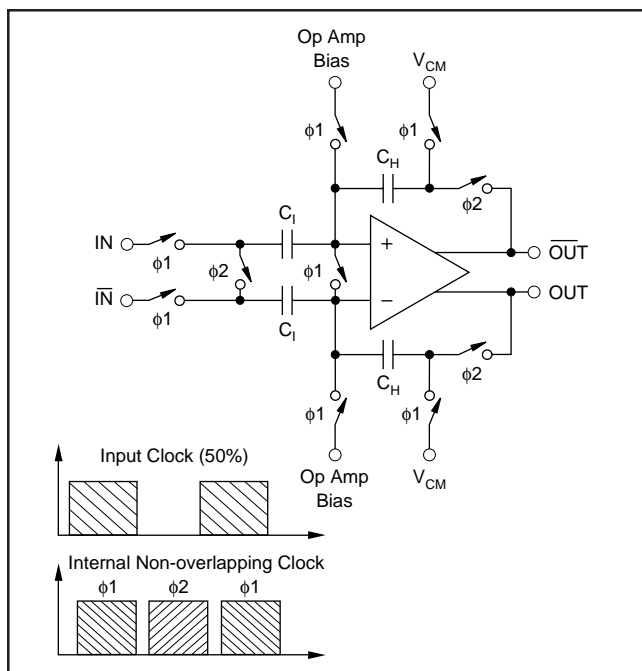

FIGURE 1. Simplified Circuit of Input Track-and-Hold with Timing Diagram.

depend on the individual application requirements and system structure. For example, communications applications often process a band of frequencies that do not include DC, whereas in imaging applications, the previously restored DC level must be maintained correctly up to the A/D converter. Features on the ADS824 such as the input range select (RSEL pin) or the option for an external reference, provide the needed flexibility to accommodate a wide range of applications. In any case, the ADS824 should be configured such that the application objectives are met while observing the headroom requirements of the driving amplifier in order to yield the best overall performance.

## INPUT CONFIGURATIONS

### AC-Coupled, Single-Supply Interface

Figure 2 shows the typical circuit for an ac-coupled analog input configuration of the ADS824 while all components are powered from a single +5V supply.

With the RSEL pin connected high, the full-scale input range is set to 2Vp-p. In this configuration, the top and bottom references (REFT, REFB) provide an output voltage of +3.5V and +1.5V, respectively. Two resistors ( $2 \times 1.0\text{k}\Omega$ ) are used to create a common-mode voltage ( $V_{CM}$ ) of approximately +2.5V to bias the inputs of the driving amplifier A1. Using the OPA680 on a single +5V supply, its ideal common-mode point is at +2.5V, which coincides with the recommended common-mode input level for the ADS824. This obviates the need of a coupling capacitor between the amplifier and the converter. Even though the OPA680 has an ac gain of +2, the dc gain is only +1 due to the blocking capacitor at resistor  $R_G$ .

The addition of a small series resistor ( $R_S$ ) between the output of the op amp and the input of the ADS824 will be beneficial in almost all interface configurations. This will decouple the op amp's output from the capacitive load and avoid gain peaking, which can result in increased noise. For best spurious and distortion performance, the resistor value should be kept below  $100\Omega$ . Furthermore, the series resistor, in combination with the 10pF capacitor, establishes a passive low-pass filter, limiting the bandwidth for the wideband noise thus, help improving the SNR performance.

### AC-Coupled, Dual Supply Interface

The circuit provided in Figure 3 shows typical connections for the analog input in case the selected amplifier operates on dual supplies. This might be necessary to take full advantage of very low distortion operational amplifiers, like the OPA642. The advantage is that the driving amplifier can be operated with a ground referenced bipolar signal swing. This will keep the distortion performance at its lowest since the signal range stays within the linear region of the op amp and sufficient headroom to the supply rails can be maintained. By capacitively coupling the single-ended signal to the input of the ADS824, its common-mode requirements can easily be satisfied with two resistors connected between the top and bottom reference.

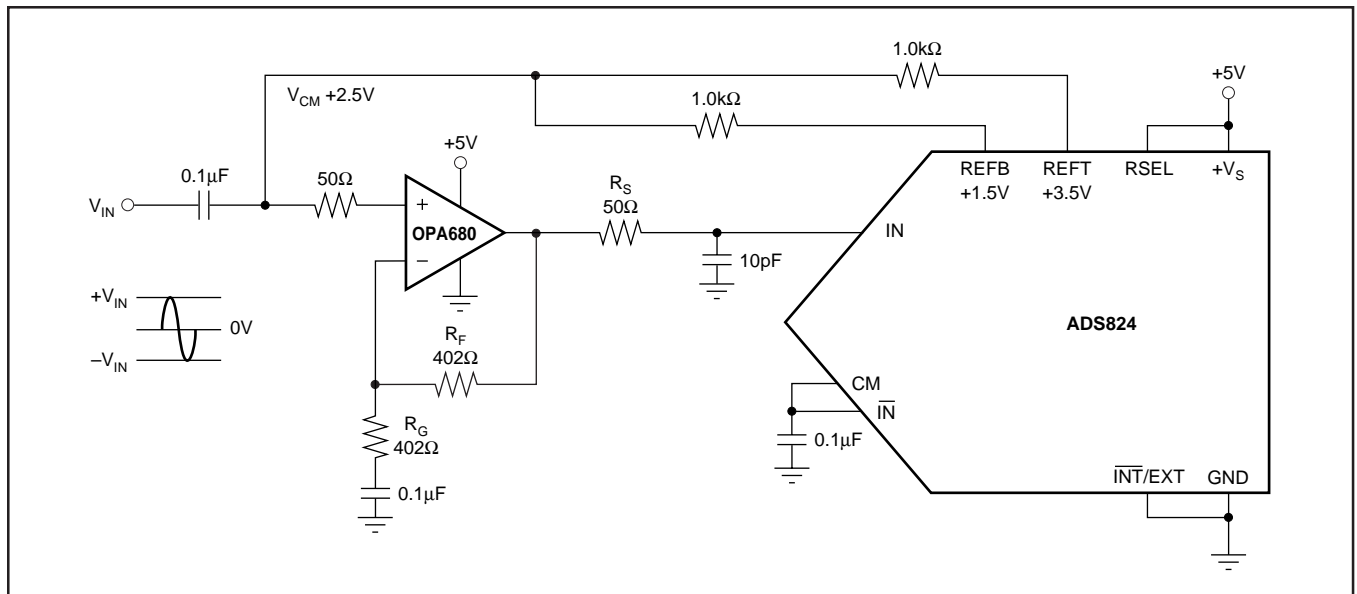

FIGURE 2. AC-Coupled Input Configuration for a 2Vp-p Full-Scale Range and a Common-Mode Voltage,  $V_{CM}$ , at +2.5V Derived From The Internal Top (REFT) and Bottom Reference (REFB).

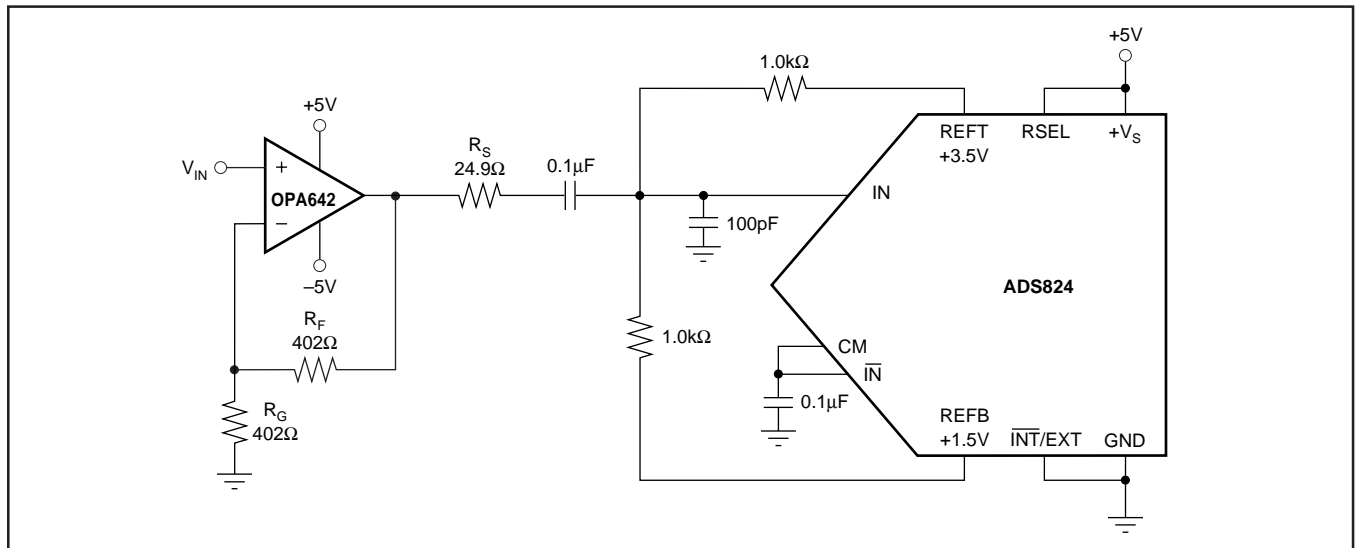

FIGURE 3. AC-Coupling the Dual Supply Amplifier OPA642 to the ADS823 for a 2Vp-p Full-Scale Input Range.

For applications requiring the driving amplifier to provide a signal amplification, with a gain  $\geq 5$ , consider using decompensated voltage-feedback op amps, like the OPA643, or current-feedback op amps like the OPA681 and OPA658.

### DC-coupled with Level Shift

Several applications may require that the bandwidth of the signal path include DC, in which case, the signal has to be DC-coupled to the A/D converter. In order to accomplish this, the interface circuit has to provide a DC level shift to the analog input signal. The circuit shown in Figure 4 employs a dual op amp, A1, to drive the input of the ADS824 and level shift the signal to be compatible with the selected input range. With the RSEL pin tied to the supply and the  $\overline{INT}/EXT$  pin to ground, the ADS824 is configured for a 2Vp-p input range and uses the internal references. The complementary input ( $\overline{IN}$ ) may be appropriately biased

using the +2.5V common-mode voltage available at the CM pin. One-half of amplifier A1 buffers the REFB pin and drives the voltage divider  $R_1$ ,  $R_2$ . Because of the op amp's noise gain of +2V/V, assuming  $R_F = R_{IN}$ , the common-mode voltage ( $V_{CM}$ ) has to be re-scaled to +1.25. This results in the correct DC level of +2.5V for the signal input (IN). Any DC voltage differences between the IN and  $\overline{IN}$  inputs of the ADS824 effectively produces an offset, which can be corrected for by adjusting the resistor values of the divider,  $R_1$  and  $R_2$ . The selection criteria for a suitable op amp should include the supply voltage, input bias current, output voltage swing, distortion, and noise specification. Note that in this example, the overall signal phase is inverted. To re-establish the original signal polarity, it is always possible to interchange the IN and  $\overline{IN}$  connections.

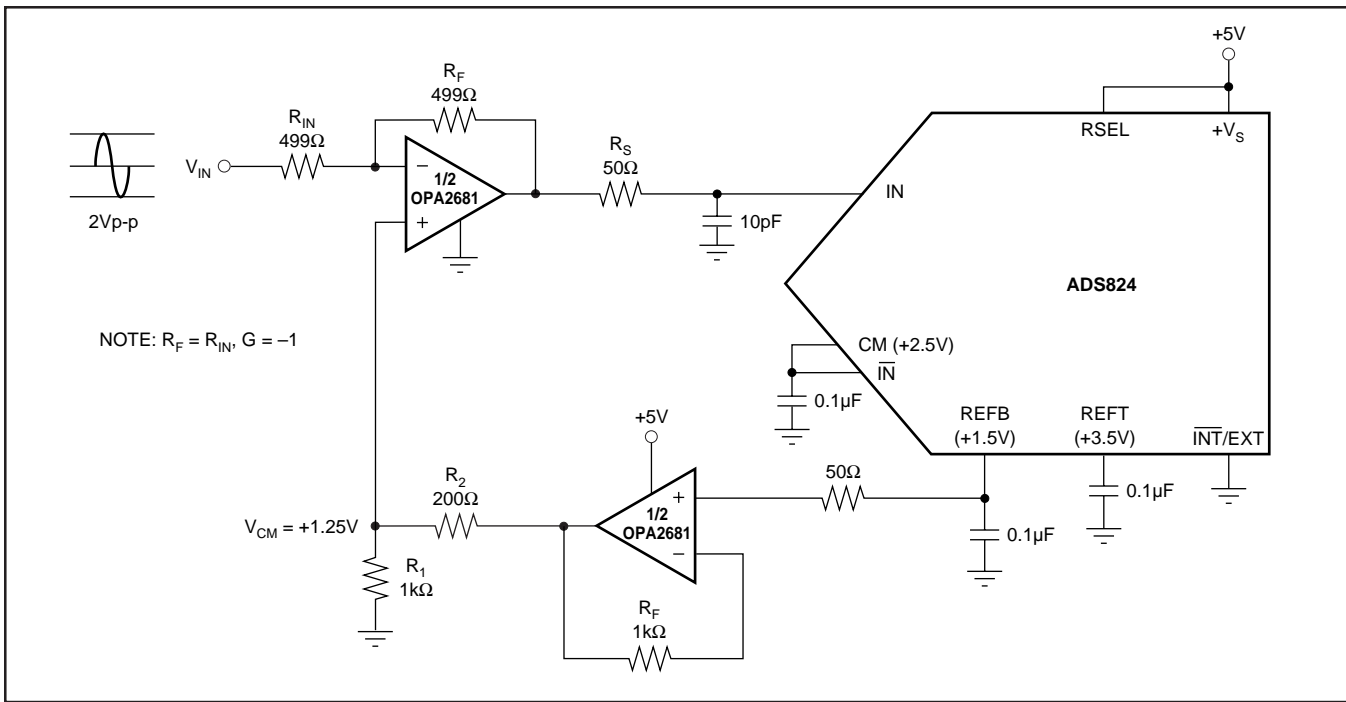

FIGURE 4. DC-Coupled Interface Circuit with Level Shifting Using Dual Current-Feedback Amplifier OPA2681.

### SINGLE-ENDED-TO-DIFFERENTIAL CONFIGURATION (Transformer Coupled)

If the application requires a signal conversion from a single-ended source to feed the ADS824 differentially, a RF transformer might be a good solution. The selected transformer must have a center tap in order to apply the common-mode DC voltage necessary to bias the converter inputs. AC grounding the center tap will generate the differential signal swing across the secondary winding. Consider a step-up transformer to take advantage of a signal amplification without the introduction of another noise source. Furthermore, the reduced signal swing from the source may lead to an improved distortion performance.

The differential input configuration may provide a noticeable advantage of achieving good SFDR performance over a wide range of input frequencies. In this mode, both inputs of the ADS824 see matched impedances, and the differential signal swing can be reduced to half of the swing required for single-ended drive. Figure 5 shows the schematic for the suggested transformer-coupled interface circuit. The com-

FIGURE 5. Transformer Coupled Input.

ponent values of the R-C low-pass may be optimized depending on the desired roll-off frequency. The resistor across the secondary side ( $R_T$ ) should be calculated using the equation  $R_T = n^2 \times R_G$  to match the source impedance ( $R_G$ ) for good power transfer and Voltage Standing Wave Ratio (VSWR).

### REFERENCE OPERATION

Figure 6 depicts the simplified model of the internal reference circuit. The internal blocks are the bandgap voltage reference, the drivers for the top and bottom reference, and

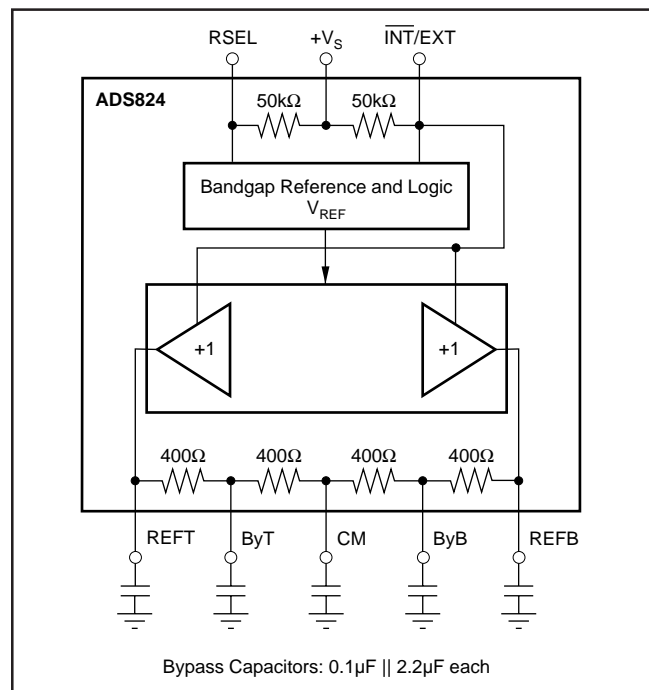

FIGURE 6. Equivalent Reference Circuit with Recommended Reference Bypassing.

the resistive reference ladder. The bandgap reference circuit includes logic functions that allows setting the analog input swing of the ADS824 to either a 1Vp-p or 2Vp-p full-scale range by simply tying the RSEL pin to a Low or High potential, respectively. While operating the ADS824 in the external reference mode, the buffer amplifiers for the REFT and REFB are disconnected from the reference ladder.

As shown, the ADS824 has internal 50k $\Omega$  pull-up resistors at the range select pin (RSEL) and reference select pin ( $\overline{\text{INT/EXT}}$ ). Leaving these pins open configures the ADS824 for a 2Vp-p input range and external reference operation. Setting the ADS824 up for internal reference mode requires to bringing the  $\overline{\text{INT/EXT}}$  pin low.

The reference buffers can be utilized to supply up to 1mA (sink and source) to external circuitry. The resistor ladder of the ADS824 is divided into several segments and has two additional nodes, ByT and ByB, which are brought out for external bypassing only (Figure 6). To ensure proper operation with any reference configurations, it is necessary to provide solid bypassing at all reference pins in order to keep the clock feedthrough to a minimum. All bypassing capacitors should be located as close to their respective pins as possible.

FIGURE 7. Alternative Circuit to Generate CM Voltage.

The common-mode voltage available at the CM-pin may be used as a bias voltage to provide the appropriate offset for the driving circuitry. However, care must be taken not to appreciably load this node, which is not buffered and has a high impedance. An alternative way of generating a common-mode voltage is given in Figure 7. Here, two external precision resistors (tolerance 1% or better) are located between the top and bottom reference pins. The common-mode voltage, CMV, will appear at the midpoint.

## EXTERNAL REFERENCE OPERATION

For even more design flexibility, the internal reference can be disabled and an external reference voltage be used. The utilization of an external reference may be considered for applications requiring higher accuracy, improved temperature performance, or a wide adjustment range of the converter's full-scale range. Especially in multichannel applications, the use of a common external reference has the benefit of obtaining better matching of the full-scale range between converters.

The external references can vary as long as the value of the external top reference  $\text{REFT}_{\text{EXT}}$  stays within the range of ( $V_S - 1.25\text{V}$ ) and ( $\text{REFB} + 0.8\text{V}$ ), and the external bottom reference  $\text{REFB}_{\text{EXT}}$  stays within 1.25V and ( $\text{REFT} - 0.8\text{V}$ ). See Figure 8.

## DIGITAL INPUTS AND OUTPUTS

### Clock Input Requirements

Clock jitter is critical to the SNR performance of high speed, high resolution A/D converters. Clock jitter leads to aperture jitter ( $t_A$ ), which adds noise to the signal being converted. The ADS824 samples the input signal on the rising edge of the CLK input. Therefore, this edge should have the lowest possible jitter. The jitter noise contribution to total SNR is

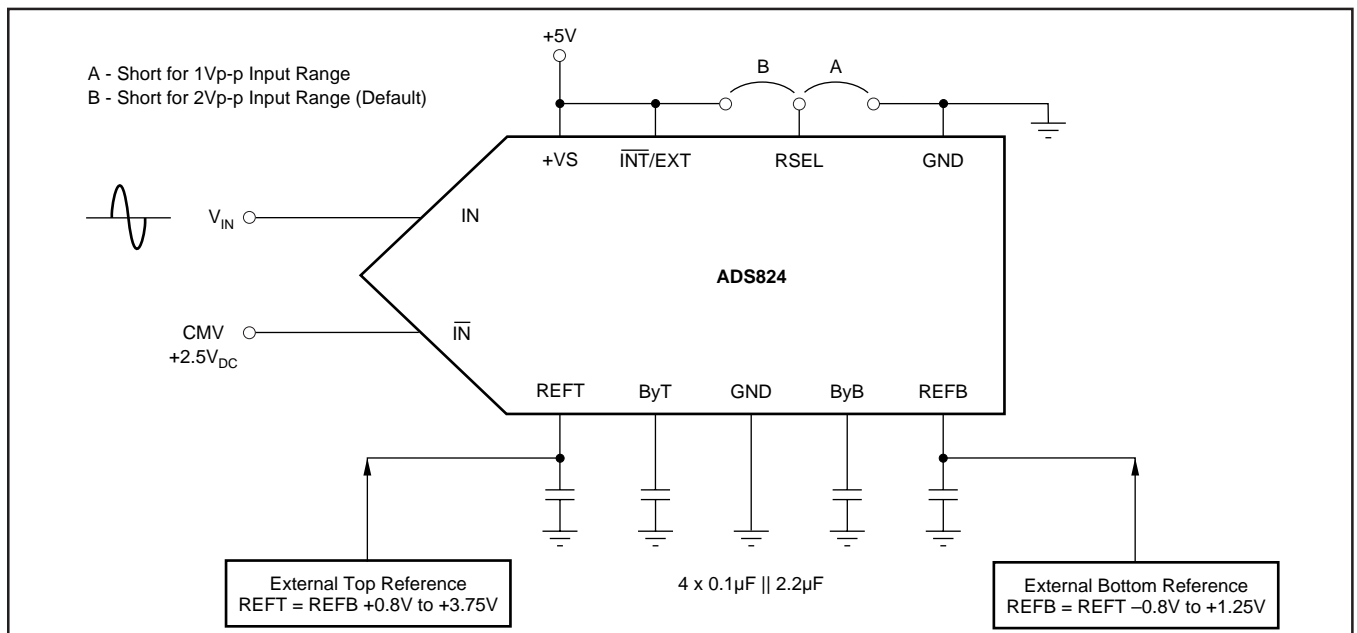

FIGURE 8. Configuration Example for External Reference Operation.

given by the following equation. If this value is near your system requirements, input clock jitter must be reduced.

$$Jitter\ SNR = 20 \log \frac{1}{2\pi f_{IN} t_A} \text{rms signal to rms noise}$$

where:  $f_{IN}$  is input signal frequency  
 $t_A$  is rms clock jitter

Special consideration should be given to clock jitter, particularly in undersampling applications. The clock input should be treated as an analog input in order to achieve the highest level of performance. Any overshoot or undershoot of the clock signal may cause degradation of performance. When digitizing at high sampling rates, the clock should have 50% duty cycle ( $t_H = t_L$ ), along with fast rise and fall times of 2ns or less.

### Digital Outputs

The output data format of the ADS824 is in positive Straight Offset Binary code, see Tables I and II. This format can easily be converted into the Binary Two's Complement code by inverting the MSB.

It is recommended to keep the capacitive loading on the data lines as low as possible ( $\leq 15\text{pF}$ ). Higher capacitive loading will cause larger dynamic currents as the digital outputs are changing. Those high current surges can feed back to the analog portion of the ADS824 and affect the performance. If necessary, external buffers or latches close to the converter's output pins may be used to minimize the capacitive loading. They also provide the added benefit of isolating the ADS824 from any digital noise activities on the bus coupling back high frequency noise.

TABLE II. Coding Table for Differential Input Configuration and  $2V_{p-p}$  Full-Scale Range.

### Digital Output Driver (VDRV)

The ADS824 features a dedicated supply pin for the output logic drivers, VDRV, which is not internally connected to the other supply pins. By setting the voltage at VDRV to

+5V or +3V, the ADS824 produces corresponding logic levels and can directly interface to the selected logic family. The output stages are designed to supply sufficient current to drive a variety of logic families. However, it is recommended to use the ADS824 with +3V logic supply. This will lower the power dissipation in the output stages due to the lower output swing and reduce current glitches on the supply line, which may affect the ac performance of the converter. In some applications, it might be advantageous to decouple the VDRV pin with additional capacitors or a pi-filter.

### GROUNDING AND DECOUPLING

Proper grounding and bypassing, short lead length, and the use of ground planes are particularly important for high frequency designs. Multilayer PC boards are recommended for best performance since they offer distinct advantages like minimizing ground impedance, separation of signal layers by ground layers, etc. The ADS824 should be treated as an analog component. Whenever possible, the supply pins should be powered by the analog supply. This will ensure the most consistent results since digital supply lines often carry high levels of noise which otherwise would be coupled into the converter and degrade the achievable performance. All ground connections on the ADS824 are internally joined together, obviating the design of split ground planes. The ground pins (1, 16, 26) should directly connect to an analog ground plane, which covers the PC board area around the converter. While designing the layout, it is important to keep the analog signal traces separated from any digital lines to prevent noise coupling onto the analog signal path. Because of its high sampling rate the, ADS824 generates high frequency current transients and noise (clock feedthrough) that are fed back into the supply and reference lines. This requires that all supply and reference pins be sufficiently bypassed. Figure 9 shows the recommended decoupling scheme for the ADS824. In most cases,  $0.1\mu\text{F}$  ceramic chip capacitors at each pin are adequate to keep the impedance low over a wide frequency range. Their effectiveness largely depends on the proximity to the individual supply pin. Therefore, they should be located as close to the supply pins as possible. In addition, a larger bipolar capacitor ( $1\mu\text{F}$  to  $22\mu\text{F}$ ) should be placed on the PC board in proximity of the converter circuit.

FIGURE 9. Recommended Bypassing for the Supply Pins.
