

## POWER MANAGEMENT

### Low Power, 5V $\mu$ P Reset

- Active LOW, Open-Drain Output
- 350ms Reset Period

The IMP1233D supply voltage monitor is an improved, low-power replacement for the Dallas Semiconductor DS1233D. Maximum supply current over temperature is a low 20 $\mu$ A, representing over 60 percent lower power as compared to the DS1233D.

The IMP1233D issues an active LOW reset signal whenever the monitored supply is out-of-tolerance. A precision reference and comparator circuit monitor power supply ( $V_{CC}$ ) level. Tolerance level options are 5-, 10- and 15-percent. When an out-of-tolerance condition is detected, an internal power-fail signal is generated which forces an active LOW reset signal. After  $V_{CC}$  returns to an in-tolerance condition, the reset signal remains active for 350ms to allow the power supply and system microprocessor to stabilize.

The IMP1233D is designed with an open-drain output stage and operates over the extended industrial temperature range. Devices are available in compact surface mount SOT-223 packages.

Other low power products in this family include the IMP1810/11/12/15/16/17 and IMP1233M.

### Key Features

- ◆ Improved Dallas DS1233D replacement
  - Over 60% lower maximum supply current
- ◆ Low Supply Current
  - 20 $\mu$ A maximum (5.5V)
  - 15 $\mu$ A maximum (3.6V)
- ◆ Automatically restarts a microprocessor after power failure
- ◆ 350ms reset delay after  $V_{CC}$  returns to an in-tolerance condition
- ◆ Active LOW power-up reset, 5k $\Omega$  internal pull-up
- ◆ Precision temperature-compensated voltage reference and comparator
- ◆ Eliminates external components
- ◆ Motorola 68xxx and HC16 compatible
- ◆ Compact surface mount SOT-223 package
- ◆ Operating temperature  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$

## Application Information

### Operation – Power Monitor

The IMP1233D detects out-of-tolerance power supply conditions. It resets a processor during power-up and issues a reset to the system processor when the monitored power supply voltage is below the reset threshold (power-down). When an out-of-tolerance  $V_{CC}$  voltage is detected, the  $\overline{\text{RESET}}$  signal is asserted. On power-up,  $\overline{\text{RESET}}$  is kept active (LOW) for approximately 350ms after the power supply voltage has reached the selected tolerance. This allows the power supply and microprocessor to stabilize before  $\overline{\text{RESET}}$  is released.
